Contents

1 Goal **1**

2 Strategy **1**

1 Goal

Software to solve the following general inverse design problem, specfically for nanophotonics.

$$\text{minimize} \quad f(x) + g(z) \tag{1a}$$

$$\text{subject to} \quad A(z)x - b(z) = 0 \tag{1b}$$

where $f(x)$ and $g(z)$ are the *design objectives* for the field (x) and structure (z) variables respectively, and $A(z)x - b(z)$ is the *physics residual* of the problem.

2 Strategy

The general strategy is to divide the problem into field and structure sub-problems, which can be tackled separately and in a modular fashion. In particular, various *field manipulators* and *structure parameterizations* can be used interchangeably to solve the respective sub-problems.

The available field manipulators are

- adjoint
- ob-1

and the available structure parameterizations include

- point
- boundary
- shape
- include/exclude
